

► Performance on the acute myocardial infarction mortality measure: **Hospitals that serve high and low proportions of Medicaid patients.**

The Centers for Medicare & Medicaid Services (CMS) periodically investigates select hospital practices that may impact a hospital's performance on the following mortality measure: hospital-level 30-day risk-standardized mortality rate (RSMR) following acute myocardial infarction (AMI) [1]. The AMI mortality measure includes Medicare fee-for-service (FFS) and Veterans Health Administration (VA) beneficiaries aged 65 or older [2]. The AMI mortality measure assesses the occurrence of death for any cause within 30 days after hospital admission for AMI [2]. The AMI mortality measure has been publicly reported on [Hospital Compare](#) since 2007 and has been included in the Hospital Value-Based Purchasing (HVBP) Program since 2013 [3].

FIGURE I Distributions of AMI RSMRs (%) for hospitals with the lowest and highest proportions of Medicaid patients, July 2011-June 2014.

Variation in RSMRs reflects differences in performance among hospitals; lower RSMRs suggest better quality, and higher RSMRs suggest worse quality. To understand the impact of caring for Medicaid patients, we examined RSMRs among hospitals with high and low proportions of Medicaid patients. Therefore, we compared the AMI RSMRs for the 242 hospitals with the lowest overall proportion of Medicaid patients ($\leq 8.4\%$ of a hospital's patients) to the 243 hospitals with the highest overall proportion of Medicaid patients ($\geq 30.5\%$ of a hospital's patients) for the July 2011 – June 2014 reporting period. Hospitals with the lowest and highest proportions of Medicaid patients are designated as those that fall within the lowest and highest deciles of all hospitals with 25 or more qualifying admissions, respectively. The proportion of Medicaid patients for each hospital was determined using the American Hospital Association (AHA) Annual Survey Database Fiscal Year 2013 [4]. To ensure accurate assessment of each hospital, the AMI mortality measure uses a statistical model to adjust for key differences in patient risk factors that are clinically relevant and that have a strong relationship with the mortality outcome [2]. Please note that VA hospitals are not included in this analysis.

TABLE I Distributions of AMI RSMRs (%) for hospitals with the lowest and highest proportions of Medicaid patients, July 2011-June 2014.

	AMI RSMR (%)	
	Lowest proportion ($\leq 8.4\%$) Medicaid patients; n=242	Highest proportion ($\geq 30.5\%$) Medicaid patients; n=243
Maximum	18.9	18.1
90%	15.3	15.7
75%	14.6	15.1
Median (50%)	13.7	14.3
25%	13.1	13.5
10%	12.5	12.9
Minimum	10.0	11.0

The median AMI RSMR for hospitals with the highest proportion of Medicaid patients was 14.3% (interquartile range [IQR]: 13.5%-15.1%). The median AMI RSMR for hospitals with the lowest proportion of Medicaid patients was 13.7% (IQR: 13.1%-14.6%; Figure 1 and Table 1).

Hospitals with the lowest proportion of Medicaid patients had a median AMI RSMR that was 0.6 percentage points lower than that of hospitals with the highest proportion.
